## FREFACE

This document is an updated version of Internal Document Econ 1.4. Its purpose is to provide SUMMARIES OF PRODUCTION TRENDS AND THE MARKET Situation of CIAT's commodities and related COMMODITIES OR INPUTS SUCH AS SORGHUM, POULTRY AND FERTILIZER.

The different sections were prepared by the COMMODITY PROGRAM ECONOMISTS ON THE BASIS OF data files and more detailed background papers WITHIN EACH PROGRAM.

In spite of extremely rapid industrial and urban growth in Latin America since World War II, one third to one half of the populations of most Latin American countries are still in rural areas. The economic and political pressures from large population sectors in rural and urban poverty are increasingly being felt. How to improve agricultural performance so that the nutritional problems of the low income groups can be improved while simultam neously slowing or at least not hastening the rural-urban migration is the present dilemma of most of the region. Continuing violence in the hemisphere indicates the importance of a solution to the increasing discontent in a rapidly changing environment.

Structural Transformation of the Latin American Economies

Rapid industriallzation and urbanization has characterized the development process in both developed and developing countries. From 1950 to 1975 the industrial sector in Latin America grew from 19 to 25 percent of gross domestic product while agriculture's share fell from 22 to 13 percent. Growth rates in industry were almost twice those in agriculture. Average labor productivity in agriculture in Latin Anerica was still only 34 percent of that in the entire economy at the end of the period (Table 1.1).

Urbanization in Latin America has proceeded at dramatic rates in the last three decades. Even though urban populations have increased at very rapid rates of 4 to 6 percent, rural populations have also continued to grow absolutely in most countries. Overall population growth, though still remaining high in comparison with other more developed regions in the world, has finally fallen slightly in the seventies (Table 1.2). The absolute growth of urban populations were staggering with an increase of 50 million in Brazil and 27 million in Mexico from 1950 to 1976 (Figure 1.1). Nevertheless, except in the countries with the highest per capita incomes over one-third and in many cases over one half of the population still remains in rural areas (figure 1.2). Since there is a high correlation between the population distribution in rural areas and in agricultural employment ( 0.87 in 1970), rural population size and
changes over time are utilized as a proxy for agricultural labor.

Ranking the Latin Anerican countries by per capita income levels gives some perspective on the structural transformation taking place. With increasing incomes the percentage of employment in agriculture fell from 49 to 16 percent whereas manufacturing increased from 11 to 18 percent. The big gainer, however, was the lower capital and skill requirements sector, which increased from 30 to 45 percent of employment, with the low skilled services as the most important component increasing from 17 to 24 percent of employment (Table 1.3). The lower capital and skill requirement sector has a higher average labor productivity than agriculture except at the highest levels of per capita income. However, in services this mean labor productivity was always lower than in agriculture over the entire income range (Table 1.4). Since this service sector was expected to be a dumping ground for much of the low income rural sector, the productivity gain from migration was much less than expected from the earlier comparisons of Table 1.1.

Structure and Performance of the Latin American Agricultural Sector:

Compared with Asia, the Middle East, and Europe, Latin America is generally considered to have large expanses of unutilized or underutilized land. Nevertheless, a large segment of the agricultural population has extremely small holdings. In 1950 and 1960, 43 and 50 percent of the farms had less than 2 percent of the land. In Mexico two-thirds of the farms had only 1.1 percent of the land in 1970. Even in Brazil with its vast frontiers 27 percent of the farms had only 1.4 percent of the land in 1970. In Argentina in 1960, 40 percent of farms had only one percent of the land (Table 1.5).

Clearly, not all the land area can be utilized for agriculture but these farm sizes were also estimated as being insufficient to earn an adequate income to support a family. This low income farm sector is expected to be the principal contributor of migrants to the urban areas. How productive is this sector and the rest of Latin American food production sector?

One crude measure of performance is the comparison of demand and supply growth. Demand growing more rapidly than supply implies upward pressures on prices or the necessity to import. Conversely, supply growing more rapidly
than demand will enable exports or decreased imports or falling prices. Technological change in agriculture is expected to enable rapid supply shifts enabling price declines and increasing consumption by low income consumers. However, the picture is further complicated by frequent governmental intervention in Latin American food prices through controls or imports to maintain low prices to urban consumers. This discourages agricultural investment and productivity growth.

In Table 1.6 the population, income elasticity, and income growth deter minants of food demand growth are presented. Except in the River Plate countries, Chile, and the Caribbean, demand growth has been very rapid, above four percent in most countries. In most countries food demand growth was greater than supply growth (Figure 1.3). Argentina has been an important exporter, Chile, Venezuela and Guatemala, have been reducing their food imports or experiencing reduced prices according to this analysis. Latin America has been self-sufficient but demand has been increasing faster than supply in both the Andean and the Central American countries.

Considering those commodities principally produced by small farmers performance has been worse. In almost all of Latin America demand has been growing more rapidly than supply. Performance has been especially poor in Mexico and Brazil apparently reflecting a policy orientation towards other crops and farm sizes (Figure 1.4).

The implications of the lagging supply growth of the principal food commodities in Latin America is serious especially given the large segments of the populations in many Latin American countries with nutritional inadequacies. What are the absolute nutritional levels and how have these been changing over time? The critical information on nutrition is the consumption levels among the low income sector and the vulnerable segments of the population especially children and pregnant women. Nevertheless, in several regions of Latin America, including the Caribbean, Central Anerica and most of the Andean countries, even the mean calorie levels are below the minimum requirements. In spite of slight improvements from the sixties to the seventies there was not much movement out of the caloric deficit for those countries with nutritional inadequacies. Over this period there were declines in the per capita consumption of roots and tubers and of dry pulses (Table 1.7).

In the last decade most of the production increase in CIAT crops has come from area expansion (this report). Corn was an exception to this as yield increases predominated. Yield increases were also very important in many countries in rice production; however, the larger area and the stagnation of upland rice production resulted in the greater importance for area expansion than of yield increase in the continent. More profitable alternatives have been forcing both beans and cassava into more marginal lands.

Over time with rising land values and the increasing prices for these basic food crops yield increasing technology will become more economically feasible. Presently, rotation between areas on the farm and between regions is often substituted for fertilization. Low densities and tolerant but low yielding materials are utilized instead of chemical control of insects and diseases. Generally, prices received by farmers are kept low by imports to benefit urban consumers or suffer tremendous cyclical fluctuation as price collapse occurs in good harvests and governments do not bother to implement price floors and storage policies.

Even with increasing land and product prices in the future, many food crops will not be produced on the prime land or by the large farmers (except when there are assured export markets) because there wlll be nore profitable alternatives with lower risk levels. Hence, it is not always necessary to make a choice between the urban consumer and the small farmer. Except where demand factors are taken care of as exports of beans from Argentina and Chile or by alcohol production with cassava in Brazil, Latin American large farmers are not expected to be interested in beans or cassava. Raising yields on small farms in these basic commodities helps resolve nutritional problems there and by raising small farmers' incomes slows migration rates.

Animal products account for almost 16 percent of total calories and one-third of total protein intake in Latin America (Tables 1.7 and 1.8 ). The relative importance of meat and milk in the diet varies quite markedly within Latin America, meat being more important than milk in most of the countries except for the Central American nations (excluding Panama), Colombia and Ecuador (Table 1.8). For low income consumers in twelve of the main urban
centers of the region, beef represented between 12 and 26 percent of their food budget and milk another 7 to 19 percent (Rubinstein and Nores) ${ }^{44}$. The importance of animal products in the consumption basket of urban families of all income groups in high, both because of its large weight in the food budget and due to the high estimated values of income elasticities of demand.

In temperate Latin America livestock production increased faster than domestic demand growth enabling increased exports or falling prices. However, in tropical Latin America demand growth was more rapid than production growth (this report). The rate of growth of the area in pastures has been inferior to the rate of growth in cattle stocks indicating a trend towards more intensive cattle production.

The comparative advantage of livestock production in tropical Latin America is expected to be in those areas with low opportunity costs, i.e. the presently marginal land areas of the "Llanos", Brazilian "Cerrado", and the Amazon region (Valdés and Nores ${ }^{52}$, pp.20-21). Often, the soils in these areas are too poor chemically to support crops without very high and probably uneconomic fertilization. In tropical Latin America there are an estimated 848 million hectares of these types of soils occupying 51 percent of the total area (Nores and Rubinstein ${ }^{39}$, p.12, estimated by Pedro Sánchez)

Thus, the Clat pasture program strategy is to increase production through new pasture technology based on grass-legume associations, selected for adaptation to acid, low fertility solls. Increased livestock production in these marginal soil areas can help release more fertile land currently in livestock for crop production in the future.

| Construction | 4.3 | 4.1 | 5.4 | 6.3 | 7.2 | 5.5 |
| Commerce | 8.3 | 8.3 | 8.2 | 11.7 | 14.2 | 10.1 |
| Services | 16.9 | 15.6 | 21.3 | 26.5 | 23.9 | 20.8 |
| Highly Skilled Service Employment ${ }^{\text {a }}$ | 5.1 | 6.4 | 4.5 | 7.8 | 13.0 | 7.4 |

a/ Includes banking, insurance, public administration, other business and goverment services.
Note: The totals may not add to exactly 100 percent due to the exclusion from the sectoral breakdown of the unemployed actively seeking work but entering the labor force for the first time. Since there are other categories in the alpha and beta sectors, they do not sum exactly to the sector total.

## Sources:

The employment data were taken from International Labour Organization, (32).

The Latin American countries were grouped according to the levels of gross domestic product per capita from the 1970 data of Inter-American Development Bank,p.396.(31). The countries in the respective categories were:
GDP/Capita Category
\$851-1200
More than $\$ 1200$

## Countries

Bolivia, Guyana, El Salvador, Honduras, Ecuador, Paraguay, Dominican Republic, Guatemala, Nicaragua, Colombia, Peru.
Barbados, Costa Rica, Mexico, Brazil.
Jamaica, Trinidad and Tobago, Panama, Chile, Uruguay Venezuela, Argentina.

The employment classifications were taken from international Labour office, p. 375 (33).

Note: The figure in parenthesis is the ratio of the sectoral labor productivity to the average labor productivity in agriculture.

Source: The labor productivities are the average productivity for that sector. They are computed by dividing the sectoral GDP as classified by the United Nations, A System of National Accounts, (48) by the sectoral employment. The figures are in constant $1973 \mathrm{U} . \mathrm{S}$. dollars. The source for the employment figures is the International Labour Organization, 1977 Yearbook of Labour Statistics, ( 32 ).
Two deletions were made in the data. The beta service sector in Peru and the commerce sector in Mexico were deleted from the group averages. The labor productivities for these two sectors were the highest in Latin America and outside expectations of range for these parameters.
table 1.5: quantification of the subsistence sector and its thportance as a share of total nurber and area in farms.

## af 1960-1975.

b/ Estimated from the proportional weights of average consumption of vegetable and animal products and the FAO income elasticities of demand.
cf Calculated as $\dot{d}=\dot{p}+E y \dot{y}$ where $\dot{d}$ is the rate of demand growth for food, $\dot{p}$ is the rate of population growith, $E y$ is the income elasticity of demand for food, and $\dot{y}$ is the rate of income growth.
d) 1966-1977.
ef The small farmer crops were defined by the USDA as maize (except in Argentina and Uruguay), rice (except in Colombia), potatoes, sweet potatoes, cassava and pulses.

## Sources:

1966-70 data based on Economic Research Service, "Agriculture in the Americas: Statistical data", pp.1-8. (10).
1971-77 data based on Economics, Statistics and Cooperatives Service, Indices of Agricultural Production for the Western Hemisphere, 1968-1977, (11).
The income elasticities of demand were estimated from food and Agriculture organization of the United Nations (FAO), (16).

## 2. ANIMAL PRODUCTS

## 2a) INTRODUCTION

Although meat consumption per head in tropical Latin America is only $26 \%$ of the level observed in North America, the distribution among different meats is quite similar (Table 2.1 and Figure 2.1). Of a total meat consumption of $28.4 \mathrm{~kg} /$ per head/year estimated in 1975/77 for tropical Latin Anerica, 16.7 kg correspond to beef and veal, followed by an almost equal share of pork and poultry meat of 5.9 and 5.1 kg respectively. Sheep and goat meat consumption per head is very similar between tropical Latin America and North America ( 0.6 and 0.8 kg respectively). The composition of meat consumption in temperate Latin America is markedly different, as beef and veal make up close to $80 \%$ of total meat consumption. In turn, sheep and goat meat consumption per head is larger than in North America or tropical Latin America, both in absolute and relative terms, particularly in Uruguay.

Within tropical Latin Anerica, the highest levels of meat consumption per head are observed in Venezuela, Panama and Brazil, followed by Mexico and Colonbia. Milk consumption per head is highest in Costa Rica, Nicaragua and Cuba (Tables 2.1 and 2.18).

Because of the different average rates of growth of production and demand observed in Latin America for the different animal products during the last decade (this report), it is expected that the relative importance of beef, poultry, pork, other types of meat, and milk may change in the future. The velocity at which this will take place will depend on how fast and efficiently each sector can adopt inproved technology and demand shifts associated with increased incomes and urbanization.

2b) BEEF

Latin America has 279 million head of cattle stock, the second largest inventory in the world after Asia. Three Latin American coumtries alone, Brazil, Colombia and Venezuela, possess $10 \%$ of the world inventories and produce $7 \%$ of world beef supply. The United States and Europe hold each around $10 \%$ of the world stock but produce together almost $37 \%$ of total annual bovine meat (Table 2.2). Although, more efficient than Asia or Africa, Latin America, especially in the tropical region, is a less efficient producer than the United States, Europe or Oceania.

During 1978, Latin America produced 8.6 million tons of beef, 118 more than the average production of 1974-1977 (Table 2.3). Beef production increased in most countries, but there were large differences in the growth rates of temperate and tropical countries. The average annual growth rate in the tropical area remained fairly constant in the 1960 1978 period at about three per cent, but it increased from 2.3\% (19601970) to 6.3 (1971-1978) in the temperate region (Table 2.4). The increase in production growth rates observed in the temperate region appears to be a consequence of the cyclical nature of the beef cattle sector (Figure 2.2).

A trend towards intensification of cattle production seems evident since growth rates in production were larger than the observed growth rates of cattle stocks (Table 2.5). Hence, production per head in stock in the temperate zone increased from $43 \mathrm{~kg} /$ year in $1974 / 77$ to $50 \mathrm{~kg} /$ year during 1978, but only from 25 to $26 \mathrm{~kg} /$ year in the tropical region (Table 2.3). This same trend is implied by the slower increase in the area in permanent pastures compared to the growth rate of cattle inventories. Area in pastures even decreased in the temperate region during this decade (Table 2.6). On aggregate, area in pemment pastures did not rise between 1974 and 1977: it decreased in Brazil and increased in Mexico (Table 2.7). An expansion of the livestock sector towards frontier
areas seems to be slowly taking place, while crops are substituting for pastureland in the more traditicalal cattle raising areas. The increase in livestock production per unit of area is a natural consequence of the increase in land values. For example, in Brazil, in the period 1966-77, the real price of cattle increased at an annual 5 : rate while the real price of pastureland rose at a $13 \%$ rate (Figure 2.3).

Because of the fast rate of population growth and slow rate of production increases in the tropical region, beef production per capita decreased from 19 to $17 \mathrm{~kg} /$ year from $1974 / 77$ to 1978 . On the other hand, the slower rate of population growth and faster rate of production growth in the temperate region resulted in an increase in production per capita from 77 to $93 \mathrm{~kg} /$ year (Table 2.8). Cattle stock per capita slightly declined in both the tropical and temperate regions during this same period.

The perfomance of the livestock sector in the tropical region is poor when compared to the growth rates of demand for beef (at constant prices). Except for Mexico, Costa Rica, El Salvador and Panama, demand for beef in the tropical countries during 1970-1978 grew faster than supply (Table 2.9). This implies an upward pressure on domestic beef prices, decreased exports, or increased imports. In the temperate zone during the same period, supply grew faster than demand, and as a result the volume of exports increased in both Argentina and Uruguay while imports decreased in Chile. Except for Chile, all countries located below the self-sufficiency line (Figure 2.4) are net exporters as expected. Between 1960/69 and 1970/78 Nicaragua and Honduras shifted from below to above the self-sufficiency line as a result of a drastic decline in the rate of growth of production, and the opposite took place with Mexico, El Salvador and the countries in the temperate region (Table 2.4). The observed increase in the growth rate of production of beef exporters appears to be a response to the dramatic increase in export prices which took place earlier in the 1970-1973 period (Figure 2.2 and Table 2.10).

As a result of increased production, and in spite of rising prices,
average per capita consumption in the tropical region remained constant and showed a strong increase in the temperate zone (Table 2.11). In Argentina, where consumer prices have been steadily rising since 1975 (Figure 2.5), per capita consumption increased during 1978 and was about maintained in 1979. The domestic price of beef in Uruguay grew event faster than in Argentina but per capita consumption remained constant. In Colombia, per capita consumption has remained unchanged in spite of the continues domestic prices increases (Table 2.11 and Figure 2.6). Brazil and Venezuela which have also undergone steady price increases, may have offset the negative effect of rising prices on per capita consumption via increased imports. During 1978, Brazil shifted from a net exporter to a net importer of beef. Using imports as a tool to close the gap between the growth rates of production and demand may prove to be unfeasible as a long-rum policy, due to the increasing balance of payments problems confronted by Brazil and other oil-importing nations.

Beef trade. Although beef is traded by many Latin American countries, beef can be considered a wage-good rather than an export commodity in tropical Latin America, except in Paraguay and Central America. During 1977/78 Brazil, Mexico and Colombia exported less than $4 \%$ of their total production (Table 2.12), although this was a period of high volumes traded and high export prices. Beef in these countries is exported as a result of favorable external prices or geographical location. Mexico exports to the United States, while Colombia benefits from its proximity to Venezuela, where most of its exports have been directed in the past years even though Venezuelan imports decreased during 1978. Brazil became a net importer in 1978 for the first time since 1970, a situation maintained during 1979 (Table 2.13).

Except for Colombia and Mexico, with almost $80 \%$ of their exports in live cattle, beef is exported by Latin American countries mainly as fresh/chilled/frozen beef (Table 2.14). But the participation of the region in the world market of this type of product has declined recently (Table 2.15). The EEC has gained control of this market (with $53.4 \%$ of world exports in 1978). Argentina and Brazil are also inportant exporters of cannod beef supplying each $25 \%$ of world exports of canned beef (Table
2.16). Participation in this market is markedly unstable (Figure 2.7). The main importers are United Kingdom, United States and West Germany.

In 1978, world beef production declined for the first time since 1971 and this decline continued during 1979, mainly as a consequence of sharp reductions of cattle inventories in North America and in Oceania, probably as a reaction to the long period of depressed prices prior to 1978. In the EEC, production rose slightly: cattle slaughter declined as a result of sone cyclical rebuilding of inventories but this was compensated by higher average slaughter weights. During 1978 beef production continued to increase in Argentina and Uruguay and only began to decline in 1979. In Argentina, beef output rose to a record level during 1978 at the expense of cattle inventories, which after expanding since the begining of the decade started to decrease during 1978.

Although world beef production decreased, the volume of trade in livestock and meat did not rise significantly during 1978, because the larger imports of the United States and the developing countries were offset by a sharp reduction of purchases by USSR and East Europe, reflecting a recovery of domestic meat supplies in the communist countries [FAO (22)].

The volume of intemational trade leveled off in 1979. Total meat exports of Australia and Argentina fell by 11 and $3 \%$ respectively from the record levels reached in 1978. Uruguay and Mexico (owing to rising domestic demand) also exported less during this year. However, there was some increase in exports from Central America and other countries. Brazil, a net exporter in the past, has been a net importer of meat since 1978. However, its imports in 1979 were not maintained at the high 1978 level. In the developed regions, USSR re-emerged as a large scale buyer.

As a consequence of the growing gap between demand and domestic supplies, United States and Japan raised considerably their beef import quotas during 1978 and even further in 1979. Prices on the United States import market have been rising from the end of 1977 until the present (Table 2.10). Since mid-1978, following the sharp increase in United

States imports quotas, and with the decline in Oceania's production, prices for Australian beef and for Argentina and other exporters have also increased though remaining considerably below those on the United States and Japanese import markets (Figure 2.8). Only in 1979 does the unit value of Argentine beef exports (in all forms, carcass weight equivalent) reach the same level as in the late 1970's and was therefore lower in real terms (Table 2.10). Thus, although the volume of trade leveled off, the nominal values of trade increased substantially. Prices on domestic markets followed rather divergent trends, rising sharply during 1978 in North American and South American exporting countries, but showing little change in Japan and Western Europe until 1979.

The above description of the latest events in the world market for beef supports the view that this market is subject to "large and erratic price changes caused primarily by cyclical changes in production in the developed nations" (Valdés and Nores, p.5). As can be seen from the coefficient of variation of real export prices (Table 2.10), prices in the market "without hoof-and-mouth disease" (United States, Japan) are more stable than those prevailing in the market "with hoof-and-mouth disease" (EEC, USSR, Near East). This may explain the higher long-rum rates of growth of production observed in Central America and Mexico, trading in the disease-free market, vis-a-vis Argentina, Uruguay and Mexico (Table 2.4) which sell most of its exports in the market "with the disease".

2c) MILK

Milk production in Latin America is very low in comparison to other regions, corresponding to less than $8 \%$ of world production (Table 2.7). Wi.thin Latin America, the tropical area supplies $80 \%$ of the region's fresh milk production, with Brazil, Mexico and Colombia being the largest producers. Argentina is the major milk producer in the temperate area (Table 2.18).

During 1978 milk production increased in all tropical countries but declined in the temperate area, as compared to the $1974 / 77$ average. This resulted in an increase of milk production per capita in the tropical area from 79 kg in 1974/77 to 89 kg in 1978, and a decrease in the temperate area from 185 to 170 kg (Table 2.18). Milk production per capita in the tropical zone is still only $35 \%$ of the milk available per person in the United States. The corresponding figure for temperate Latin Anerica is $52 \%$ of apparent United States per capita consumption (Table 2.18). Production per milking cow in the temperate zone is twice that of tropical Latin America (but still very low in comparison with the United States), which may be partly explained by the difference in cattle breeds and the higher specialization of this sector in the temperate zone (Table 2.19).

In Brazil, pure milking cows represent only $15 \%$ of the total breeding herd. Yet dual-purpose herds are $35 \%$ of the nation's breeding stock and supply from 20 to 35 , of total milk and milk products (Rivas and Nores, p.11). In the North Coast of Colombia, the country's main cattle raising area, $66 \%$ of beef cattle ranches can be classified as milk producers. In contrast, milk production with beef cattle herds is almost non-existent in the tenperate zone. Milk production from beef cattle herds in tropical Latin America should not be overlooked as an important product.

Average productivity in milk production has remained virtually
stagnant since $1961 / 65$, changing from 956 to 970 kg /animal, with cyclical fluctuations around these values (Table 2.19).

The production of milk in Lat in America during the period 1970-78 grew at an annual average rate of $5.5 \%, 6.6 \%$ in the tropical area and only $0.1 \%$ in the temperate zone. During this period, the highest rates of growth in production were observed in El Salvador, Bolivia and Mexico, while growth rates were negative in Peru, Colombia, Guyana and Chile (Table 2.20). Although production increased fairly rapidly during this decade, there was also a rapid increase in the demand for milk. Paraguay, Mexico, Bolivia, Nicaragua and El Salvador have recently achieved growth in milk production exceeding the rates of growth in demand (Figure 2.9). If production continues to grow at its 1970-78 rate, production in these countries will exceed projected consumption in the long-run. The higher rates of growth in milk production observed in the last few years appear to be, as with beef, more a result of the cyclical nature of the cattle sector than a consequence of increase productivity, as indicated earlier by the almost unchanged volume of production per milking cow.

Latin America is a net importer of milk: Mexico, Venezucla and Cuba import more than half of all imports of dry milk (Table 2.21). In 1978, imports reached 326,136 ton of dry milk. Trade in liquid and condensed milk are of lesser importance. Nicaragua and Costa Rica are the only net exporters of milk.

Because of direct government intervention in the domestic markets for milk, changes in the price of milk over time often do not reflect the gap between supply and domestic demand. Nevertheless, the real price of milk has risen during this decade (Table 2.22). Milk is relatively cheaper in Brazil and more expensive in Venezuela, in comparison to beef. The beef/milk price ratio in selected countries ranged from around 4 to 6 during 1978, showing less divergence between countries than in earlier years (Table 2.23).

Figure 2.9 Fresh milk: growth rates of production and demand in Latin America, by

Source: Table 2.20

## 2d) SWINE

The swine population in Latin America is $10.2 \%$ of world swine inventory, larger than that of the United States, Africa and Oceania put together, but half that of Europe (Table 2.24). Yet, it supplies only 4.4\% of world pork production, which is one third of production in the United States. Brazil, Mexico and Argentina dominate the market with $60^{\circ}$ of Latin American production. Two other tropical countries, Colombia and Venezuela, follow with 9.2 : of production (Table 2.25). These countries are also the main producers of animal feed such as maize or sorghum.

Production per head in stock in the tropical region is half that of the temperate zone. Productivity levels in Ecuador, and some Central American countries are extremely low. Countries with the highest extraction of pork per head in stock during 1978 were Argentina ( 56 kg ), Colombia ( 52 kg ) and Paraguay ( 51 kg ) (Table 2.25).

Pork production has either increased or remained stagnant over time, except in Chile, Uruguay, Guatemala and Honduras where production has decreased in the 1970-78 timespan. From 1970/74 to 1975/76 only Colombia, Venezuela and the temperate zone had shown noticeable improvement in swine productivity ( 1979 CIAT Trend Highlights). However, from 1975/76 till 1978 this trend was reversed, with productivity declining in the temperate zone but increasing in some of the tropical countries such as Brazil, Mexico and Costa Rica (Table 2.25). In Paraguay, the country with the highest per capita consumption in Latin Anerica (Figure 2.10), total production increased somewhat but at the expense of inventories. In Fcuador, the absolute level of production decreased (although inventories increased) reaching a low extraction of 11 kg of meat per head in stock during 1978. Both stock and production decreased in Argentina.

Trade in pork continues to be unimportant in the region, except in
the cases of Venezuela and Panama in 1978 which imported around $10 \%$ of their pork. Brazil, Mexico and Argentina export very small amounts of pork, but the region is on average a net importer (Table 2.26).

In spite of the fact that production in Brazil, Mexico and Colombia has increased (Figure 2.11), output per capita has remained stagnant (Brazil, Colombia) or even slightly decreased (Mexico). With the exception of Paraguay, production per capita fluctuates between 2 and 7 kg in the tropics, and between 3 and 9 kg in the temperate region. These levels have been much the same in the last 20 years (Table 2.27). The long-run growth rates of demand and production during 1960-1976 have been almost identical (Rivas and Nores, Table I.8), but this trend seems to be changing during the last decade, with production growth rates declining vis-a-vis a sustained demand growth (Table 2.28). This is true for both the tropical and temperate regions. The highest rates of growth in production during the 1970-1978 period were found in Paraguay, Venezuela, Colombia and in a few Central Amorican countries. Recently growth rates have decreased substantially in the three largest producing countries: Brazil, Mexico and Argentina, as well as in some other smaller countries. In Argentina and Mexico, maize production (major animal feed) decreased in the period from 1971/73 to 1976/78 (Table 6.4). In Argentina, a net exporter of maize, exports increased in spite of the decline in production. In Mexico, as production stagnated, maize imports were substantially increased. Thus, it is possible that prices of foed grains have been under upward pressure in both countries. This has clearly occurred in Brazil. The relative price of concentrates increased in Brazil during the period 1970-1978 (Figure 2.12). This may have contributed to the slower growth rate in swine production in recent years.

In Colombia and Venezuela the situation is different as production growth has accelerated during the last years (Table 2.28). Although growth rates of naize production are rather low in these countries, sorghum production has increased dramatically (Table 6.5). The profitability of swine production in Colombia has clearly improved, as shown by the rising swine/concentrates price ratio (Figure 2.12).

The price of pork (in dollars) has increased, in Brazil, Venezuela, Argentina and Colombia (Table 2.29). Moreover, the beef/pork price ratio has gone down in these same countries (Table 2.30), except in Colombia, where it has remained fairly constant over time. In relation to poultry, pork has become more expensive in Brazil [F.G.V. (27)] and in Colombia (Figure 2.13). The same trend could be occurring in other countries in part as a result of the superior feed conversion efficiency in the production of poultry.

2e) POULTRY

Latin America has 128 of world poultry inventories, 785 million head, but produces only $8 \%$ of world poultry meat production. The United States possesses $6 \%$ of the world stock and supplies almost $30 \%$ of world poultry meat (Table 2.31).

Ninety two percent of the Latin American poultry stock is found in tropical Lat in America which supplies $84 \%$ of Latin American production. Brazil and Mexico dominate production. In 1978 they supplied more than half of the region's poultry meat, followed in importance by Argentina and Venezuela. All of Central America produced less than Venezuela alone (Table 2.32).

Latin America is a net importer of poultry, although Brazil and Argentina export around 7\% of their production. Venezuela imports $12 \%$ and Mexico $2 \%$ of their internal consumption. Uruguay is the only other exporting country in the region, trading $12 \%$ of its production in the world market.

Growth in poultry production has resulted both from growth in stocks and from the adoption of modern technology. During the period 1961/1971 to 1978, Latin American poultry stock increased at an annual average rate of $4.9 \%$, and production grew at $9.5 \%$ annually (Table 2.33). Both stocks and production grew faster in the tropical region, particularly in Brazil, Mexico, Venezuela, Ouba and El Salvador (Figure 2.14). Chile is the only country where production dec1ined during this period.

As a result of the high rates of growth in production, supply has increased faster than demand during the 1970-1978 period, with the exception of Ecuador, Bolivia, and some Central American countries (Table 2.34). If these growth rates are maintained in the future several countries would becone self-sufficient or even net exporters of poultry
(Figure 2.15). As a result, the relative price of poultry has declined over time. In Brazil, the beef/poultry price ratio increased at a $1.3 \%$ annual rate over the 1970-1978 period [F.G.V. (27)].

Nevertheless, the efficiency of the poultry sector in Latin America is still very low, producing 2.3 kg and 5.5 kg per head in stock in the tropical and temperate regions respectively. The United States produces 20 kg per head in stock (Table 2.35). In Latin America, Argentina has the highest productivity ( $7.9 \mathrm{~kg} /$ head) followed by Venezuela ( $6.3 \mathrm{~kg} /$ head). Central Anerica, Bolivia, Ecuador and Colombia are the most inefficient. But the high rates of growth observed in the last decade and the fact that no poultry data were published for Latin America prior to 1969 indicates that this is one of the most dynamic sectors of animal products in the region. Brazil, for example, was a net importer of poultry until 1974. It became an exporter in 1975, and by 1978 Brazil became the fifth exporter in the world, after Canada, United States, EEC and Hungary. The profitability of poultry production is expected to be higher in Brazil than in other countries of the region. In 1978 the Brazilian producer could buy 4 kg of concentrates with one kg of poultry meat, while the Colombian producer could only buy 3 kg of concentrates. The poultry/concentrate price ratio is even more favorable in Chile, where poultry production increased by more than 308 in 1978, after several years of low production (Figure 2.16).

Per capita poultry consumption in the tropical region is half that of Argentina, and only $14 \%$ of per capita consumption in the United States, with the exceptions of Venezuela, Guyana, Cuba and Peru (Table 2.36). The high and steadily rising levels of per capita consumption in Venezuela ( 17 kg in 1978) is due to increased imports, which were increased substantially in 1977 and further in 1978. This may be a consequence of the declining poultry/maize and poultry/sorghum prices which have taken place in Venezuela during the last years (Figure 2.17). Poultry production during 1978 did not exceed that of 1977, although it had been increasing in the previous years (Figure 2.14). In general, consumption is much lower in Central America, Bolivia and Ecuador, which as mentioned earlier, are also less efficient producers. Overall,
poultry consumption per capita in Latin America has increased over time (Table 2.36).

## 3. Beans

Brazil and Mexico dominate production with 75.5 percent of Latin American production. Two of the three principal bean exporters, Argentina and Chile, follow with 7.5 percent of production (Table 3.1). Latin America remains a small net exporter of edible legumes with substantial exports by Argentina, Mexico, and Chile and large imports by Cuba and Venezuela (Table 3.2).

Bean production has been stagnant with continuing yield declines in Latin America ( $-0.8 \%$ ) and a rapid decline in Brazil ( $-3.0 \%$ ) (Figures 3.1 and 3.2). Production has been maintained by area increase especially in Brazil (2.5\%). Even in the principal agricultural states of Brazil, Parana and Säo Paulo, bean yields remain low (Table 3.3). Mexico has been able to increase yields but area has declined rapidly there.

In 1979 there has been a decline in both Brazilian and Mexican bean production. In Brazil the gradual production decline over the last two harvests continued with a slightly falling area in the Central South (Table 3.3). In the 1979 "safra da agua" production has again fallen (Veja", p.83). In Mexico the bean harvest of 1979 of 638,000 tons was 32 percent lower than in 1978 implying a need to import 250,000 tons to maintain 1978 levels. (The Economist Intelligence unit ${ }^{12}$, p.16).

Bean production has not been stagnant everywhere. Argentine and Colombian production has increased rapidly largely due to a strong export demand for European and Venezuelan markets respectively. El Salvador also has exported beans to Guatemala and has an impressive rate of production growth (Figure 3.4).

High population and per capita income growth kept demand growth above three percent in most Latin American countries. In few countries did production grow sufficiently rapidly to accompany demand so some combination of rising prices, increasing imports, and decreased per capita consumption especially among poorer consumers were experienced by most countries in Latin Anerica (Table 3.4 and Figure 3.5).

Only in Colombia and Mexico have bean yields been increasing significantly and absolute levels are still extremely low except in the temperate countries
(Table 3.5). Production increase or maintenance with falling yields have been achieved with rapid area expansion (Figure 3.6). As beans are pushed into more marginal areas further from the principal markets and prices go up the potential returns to yield increasing technology are also increasing. Production stagnation appears to be principally a supply problem. However, governments can help avoid price collapse in the limited domestic markets by price floors in good harvest years. More rapid income increase in the poorest sectors of the Lat in American economies would also be expected to substantially increase demand growth.

a/ Cowpeas were deleted from the Brazilian bean production estimates. Cowpeas were an estimated 22.5 percent of bean production in the Brazilian Northeast and 7.5 percent of total Brazilian bean production. These estimates were based upon beans and cowpeas maintaining the same production shares as in the 1966-1977 period according to unpublished CFP (the Brazilian Commission for Financing Production of agricultural commodities) data.
b/ Includes those countries producing less than 0.5 percent of Latin American production in 1976-1978.

## 4. Cassava

Since cassava is a root crop, it is a very efficient producer of carbohydrates. Moreover, it is particularly well adapted to marginal agricultural conditions, producing relatively good yields under stress due to soil and climatic factors. However, upon harvest it is highly perishable, contains $60 \%$ water or more, and is extremely bulky withminimal storage potential. Thus, quite favorable production characteristics constrast very sharply with very unfavorable market characteristics. Quite simply, cassava is an ideal rural subsistence crop but is a high priced vegetable crop in urban markets due to marketing problems. With the high cassava price in urban markets cassava loses its comparative advantage to grains, due to their lower marketing margins. Food uses, predominantly in rural areas, determine the demand for cassava in Latin America.

The growth in cassava production has not kept pace with the rates of growth in the production of grains. Cassava production in Latin Anerica in the $1960-78$ period increased at only $1.9 \%$ per annum, well below the population growth rate of $2.8 \%$ (see Table 4.2). This large implicit gap between supply and demand raises two hypotheses. The first assumes conssrraint on the production side and asserts that the lag in production growth generates rising prices and that the lack of supply response is due to constraints on area expansion or lack of yield increasing technologies. The second hypothesis assumes that the principal constraint is on the demand side and suggests that demand is growing at less than the population growth rate. The potential impact of new technology on traditional cassava food markets obviously depends on which hypothesis is operative.

No reliable conclusions can be drawn from the aggregate data other than that production has been growing very slowly or even declining in the 1960-78 period, with this trend being especially dramatic in the 1970-78 period. Table 4.2 suggests a virtual stagnation in the cassava economies of the major producing countries in the $1970-78$ period, with area remaining relatively static and yield actually on a declining trend. Colombia would appear to be an exception, but continued high prices in Colombian cities and no apparent market outlet for the growth in production raises doubts about the reliability of an estimated $6 \%$ rate of growth in the $1960 / 78$ period.

Brazil, which produces $80 \%$ of Latin American production, offers some independent data sources that allow perspective on the demand side. Table 4.4 presents the results of two consumer food budget surveys conducted in 1960 and 1975. Three principal points are highlighted by this particular table: (1) a large diffexence in consumption patterns of cassava between rural and urban areas, (2) a marked tendency to consume cassava in principally flour form, and (3) a significant decline in per capita consumption levels between the two periods in almost all categories.

Demand factors appear to be limiting expected price rises in cassava. One factor is the shifting population distribution to urban areas, where grains have the comparative advantage as the carbohydrate staple. A second factor is the substitution possibilities as prices rise. Table 4.5 demonstrates that cassava prices, especially for flour, did start to rise quite sharply in 1975, continuing though to 1976. In 1969 and 1970 the farinha to wheat flour price ratio hovered around .5. In 1975 it was a little over 1.0 in most Brazilian cities and by 1976 over 2.0 . While cassava flour
consumption was declining, wheat flour consumption increased $23 \%$ between 1975 and 1976. Thus, the decline in cassava consumption in 1975 is at least partially due to an own price rise and a substitution effect. The third demand factor could be a low income elasticity, at least for flour. A low income elasticity may not apply to fresh cassava as there were increases in per capita consumption levels in the urban areas in the Northeast and South.

Rising prices together with declining production are reducing the role of Brazil in cassava export markets (see Table 4.6). Moreover, growth in export markets have seen a relative shift away from starch toward pellets as an animal feed component, almost wholly as a result of price policy in the EC market. This market has been captured almost entirely by the Far East, principally Thailand.

Thus, cassava in Latin America is following much the same pattern as maize where it goes principally into food uses (see section 6). That is production appears to be stagnating due to lack of demand growth. A significant growth market for cassava products is needed. This may be provided in Brazil by the alcohol program. As well, within Brazil the economic rationality of a policy that stibsidizes wheat both on the production side and on the consumption side, therefore effectively discriminating against the consumption of a domestically produced alternative, is not clear. Outside of Brazil market growth will probably come in the animal feed sector, as has happened in maize. However, to competitively exploit these markets, yield increasing technology and processing technology will be required.

## 5. Rice

Rice is rapidly becoming the principal carbohydrate staple in much of Latin America. It is effectively displacing maize in many countries in Central America and the Andean region and root crops in the Caribbean and the Andean zone. This fact is reflected in the relatively high income elasticities for rice, as shown in Table 5.5. As the Latin American economies progressively urbanize, this tendency will continue as urban consumers turn to rice as a primary staple and away from the dominant rural staples, maize and cassava.

Latin Anerican rice production has been increasing at an annual growth rate of $3.3 \%$ in the $1961 / 78$ period (see Table 5.2). Production growth rates have far exceeded population growth rates in all regions except Brazil, which, however, accounts for almost $60 \%$ of total Latin American production, Latin American has in the process shifted from being a net importer of rice to a net exporter, while at the same time increasing per capita consumption levels from 41 to 44 Kg per person from 1971/73 to 1976/78 (see Table 5.4). The only region that remains a net importer is the Caribbean, although even in this zone import levels have been falling.

As shown in Table 5.5, production growth in the major regions, except for Brazil, has been either in line with demand growth or well ahead. The production growth appears to be at least partially demand led and in areas where production has exceeded demand growth, new technology has allowed falling prices (to at least the world market level) while maintaining production incentives. The River Plate countries are an exception in that their agricultural economies are open and thus already operate at world market price levels. Only in Brazil do there appear to be obvious cons-
traints on production increases.

In Mexico, Central America, Venezuela, and the Andean Zone production growth has been due principally to rising yields. With the exception of Central America, these yield increases have come principally from irrigated land (see Table 5.6). Central America, on the other hand has achieved quite marked yield increases under primarily upland conditions, although obviously starting from a much lower average yield level than the other regions. Thus, yield increments are being achieved under both irrigated and favorable upland conditions. In The River Plate countries, on the other hand, production growth has resulted from area expansion principally on irrigated areas. Moreover, The River Plate countries have consistently maintained relatively high yield levels with little variation.

Brazil also has been dependent on area expansion to sustain its $2.2 \%$ growth rate in production. However, average yields are at very low levels and have declined slightly over the period. This appears to be due to the declining area planted to irrigated rice and the rapid expansion in upland rice (Figure 5.2). The principal area expansion has been in the interior states of Mato Grosso, Minas Girais, and Goias (Anuario Estadistico do Brazil). Yields in these states are very low, principally because these areas are characterized by acid, infertile soils. In these states rice is used as a first crop to bring new land into pasture production and takes advantage of the higher initial soil fertility. Responsiveness of supply under these circumstances would be expected to be low as increments in rice production would be due to investment patterns in developing new pasture land.

Figure 5.1 . RICE: average yields in Latin America and the two major producing countries

Figure 5.2 PRODUCTION STATISTICS FOR BRAZIL 1969-78

Maize is an important crop throughout much of Latin America and the Carribbean, being variously a major food staple, an animal feed, as earner of foreign exchange, or, frequently, the source of a substantial foreign exchange deficit.

The production of maize is concentrated in three countries (Table 6.1). Brazil produces about two-fifths of the total regional output, while Mexico and Argentina each produce about a fifth of the total. These same countries are also heavy consumers of maize. Mexico has the largest per capita annual consumption of maize, 164 Kgs. , while Brazil is second at 149 kgs . and Argentina is close behind at 123 Kgs . Venezuela and most Central American countries also consume on the average over 100 Kgs . per capita annually. Maize consumption is much lower in the Andean and Caribbean zones.

## Trends in Production

Most Latin American countries have experienced significant growth in the production of maize between 1961-1978 (see Table 6.2). Of twenty four nations considered, 17 have had significant growth rates in this period. There are, though, some important contrasts in the patterns of growth. For example, although the output of the top three producers grew in this period, Brazil's grew steadily at a rate of $3.7 \%$ annually through the entire timespan, but Mexico and Argentina acheived growth only during the $1960^{\prime}$ s and have faced declining or stagnant production in the 1970's.

Paraguay and El Salvador, like Brazil, have enjoyed rapid growth over the last two decades. Production has increased less dramatically but nevertheless steadily in Bolivia, Chile and Peru. Joining Argentina and Mexico
in the ranks of those who have not sustained their growth in the $1970^{\prime}$ s are Venezuela, Colombia, Ecuador, and several of the Central American states.

For Latin America as a whole, there was an increase of $54 \%$ in total production of maize in the $1960^{\prime} \mathrm{s}$. However, through the $1970^{\prime} \mathrm{s}$, there was a growth in total output of only $7 \%$. Thus, although there has been a widespread rise in maize production in Latin America from 1961-78, the record of recent growth has been relatively poor.

Sources of Trends in Production
Nearly three quarters of Latin American countries have achieved significant growth rates in yields over the last two decades (see Table 6.3). Of the major producers, Argentina has attained the most rapid rate of growth in yields and today has the highest yields in Latin America. Brazilian yields have grown comparatively slowly, but have continued to rise throughout. the period 1961-1978. Mexico, like Chile, obtained substantial yield increases in the $1960^{\prime}$ s, but has made no gains in the last decade.

Areas planted to maize, have not, however, expanded steadily along with yield growth (see Table 6.2). During the $1960^{\prime} \mathrm{s}$, area planted to maize grew substantially in Latin America as a whole, and accounted for over half of the increased output that was acheived in the decade. In the 1970's, though, area expansion ceased in most countries, and the growth rate in production slowed as it became dependent on increased yields alone. Brazil is almost unique in maintaining growth in area as an important contributor to increasing production.

In many countries, among them Argentina, Venezuela, Colombia, Peru,

Ecuador, Guatemala and Uruguay, area planted to maize declined in the 1970 's. Since the land that was taken out of production may have generally been of lower than average quality, improvements in technology, i.e. new varieties and more chemical fertilizers, may not be the sole cause of the yield increases observed in these countries.

Growth rates in production seem to be related to the end use of maize (see Table 6.5). Among the countries that consume maize primarily as a direct component of the human diet, growth rates in the production of maize are generally quite low as is the percent of total consumption that is imported. Among the nations where more than half of maize is used as an animal feed, both rates of growth and imports as a percent of total consumption are high.

Where maize is consumed as a carbohydrate staple, much production takes place in a subsistance agricultural sector of small farms and a large portion of output is consumed directly by producers without entering the market. In this setting of small farms, which are poorly integrated into markets and of ten located on the more marginal soils, production has not risen dramatically $1 /$.

Where maize is used primarily as an animal feed, effective market demand for maize has been strong enough to attract supplies either through imports or through increased domestic production. Domestic production of maize as a feed grain has tended to rise among more comercialized larger

1/ Cutie, Jesus, "Diffusion of Hybrid Corn Technology: The Case of El Salvador", CIMMYT, Mexico 1975 and Colmenares, J. Humberto, "Adoption of Hybrid Seeds and Fertilizers Among Colombian Corn Growers", CIMMYT, Mexico, 1975.
farms, better served with infrastructure and cultivating fairly good soils. Such has been the case in Brazil, where the major part of the production increase has come in the Southeastern states, where mechanized production and hybrid utilization predominates.

In some countries where maize output has not been growing rapidly, sorghum has been a very successful alternative feed grain which has acheived some strikingly fast rates of growth in production (see next section, 7).

Trade Balances
Argentina, Brazil, Uruguay and Paraguay are the only Latin American exporters of maize (Table 6.4). For Argentina, maize is an export crop. About three-fifths of the Argentine maize crop is exported. The other exporting countries sell abroad no more than five per cent of their output. Argentina supplies over $90 \%$ of all maize exported from Latin America, and alone exports more maize than is imported by the 19 countries in the region, which are net importers. Hence, although Latin Anerica as a whole is an exporter of maize, this export surplus originates almost entirely in Argentina while most Latin American countries are maize importers.

Mexico is by far the greatest importer of maize in Latin America even though it is one of the leading producers. Mexico's imports of maize declined in the late $1960^{\prime \prime} s$ at the end of decade of fairly rapid growth in production. However, during the $1970^{\prime}$ s production stagnated and imports grew tremendously, so that now Mexico must import approximately one sixth of its main dietary staple at a large cost in foreign exchange.

Like Mexico, Colombia, Peru and several of the Central American states improved their balance of trade in maize during the high growth of maize
production in the $1960^{\prime}$ s, only to see these gains erode during the slower growth of the $1970^{\circ} \mathrm{s}$.

The burden of maize imports fall relatively most heavy in the Caribbean zone. With the exception of Haiti, all the Caribbean countries import far more than their levels of domestic production of maize even though per capita consumption is comparatively low (Tables 6.5).

## 7. Sorghum

Sorghum is a feed grain which has become a major crop in Latin America cnly recently. Two decades ago sorghum production in Latin America was less than a tenth of maize production but today it is nearly a third. The growth in sorghum output has been extremely rapid. At the beginning of the sixties about two million tons of sorghum were produced in Latin America (Table 7.1). By the early seventies production has risen to 7.5 million tons, and Latin American sorghum production currently exceeds 12 million tons annually.

Argentina is the main producer of sorghum, contributing over half of the regional output while Mexico is second with about a third. Brazil, which is the top Latin American producer of rice, maize and cassava, is a very poor fourth in sorghum, with only three per cent of the regional output. Per capita consumption of sorghum is highest in Argentina and Mexico, the main producers, and also in venezuela which can afford to import substantial quantities. For the entire region, however, per capita consumption of sorghum is considerably less than for cassava, maize or rice.

## Trends in Production

Rates of annual growth in output of sorghum are very high and far greater than for the other products considered in this report. Production rose at an amazing $13.7 \%$ per year in Latin America from 1961 to 1978 (Table 7.2). The highest growth rate was acheived in Venezuela, $30.6 \%$ and Colombia was second at $25 \%$. The largest producers, Argentina and Mexico, also attained very strong growth rates of 15.8 and 11.1 per cent respectively, from fairly substantial base year figures. Growth rates were higher in the sixties than in the seventies since many nations produced little or no sorghum at the beginning of the period. Nevertheless, the average annual
absolute increase in output for the entire region has remained nearly constant over the last two decades.

Increase in area cultivated has been the most important factor in growth of production. Over two third's of the gains in output have come from expansion of area. Although in Colombia and Venezuela area expansion is practically the sole factor in the rapid growth in production, Mexico and Argentina have coupled modest but steady growth in yields with strong increases in area.

Sorghum yields are considerably higher than maize yields for most countries in the regiun. Average yield of sorghum is 2.6 tons per hectare, compared with 1.5 tons for maize. Moreover, while sorghum yields have gone up about a ton in the last two decades, maize yields have risen by only about one third of a ton.

## Trade Balances

Latin Anerica was a net exporter of soxghum is 1976/78 (Table 7.4). However, as is the case with maize, Argentina alone accounts for more than $90 \%$ of Latin America exports. Moreover, Latin American sorghum importers outnumber exporters in the region by almost three to one. Mexico imports more sorghum than any other Latin Anerican nation, purchasing $12 \%$ of its apparent consumption. Mexican imports have increased dramatically during the seventies despite significant gains in production. Venezuela is the second greatest importer, in absolute terms, and it buys $62 \%$ of its apparent consumption. Like Mexico, imports have continued to climb in Venezuela even though production has expanded substantially.

With the exception of Venezuela, sorghum imports are at a much lower
level than imports of maize and consequentiy are not a major balance of payments problem for most Latin American countries. Since imports have persisted in growing in many countries despite rapidly increasing domestic production, sorghum imports may develop into a more serious problem if recent trends are maintained.

8. Fertilizers

The substitution of fertilizer for area expansion will depend upon the original soil fertility, the relative prices of land and fertilizer, and the profitability and fertilizer response of the crops planted. With abundant land and little production capacity of fertilizers utilization has been very low compared with the countries with scarce land resources such as Japan and West Germany. In many countries of Latin America rotation and area expansion have traditionally been relied upon rather than fertilization. In the last two decades there has been a rapid increase in Latin American fertilizer consumption principally in the countries producing part of their own fertilizer requirements. This increase has been especially rapid in Brazil and Mexico. El Salvador and Costa Rica, with their high man-land ratios have also attained high rates of fertilizer consumption per hectare (Table 8.1).

From 1965-66 to 1977-78 Latin American consumption of nitrogen fertilizers more than tripled; however, production increased faster than consumption so the dependence upon imports was reduced from 70 to 52 percent. During the same period Latin American consumption of phosphorus fertilizers increased by almost five times. Dependence upon imports increased from 52 to 68 percent (Table 8.2). Most countries in Latin America imported substantial quantities of fertilizer (Table 8.3); nevertheless, the Latin American fertilizer market share is still very small. In 1977-78 Latin America consumed 5.4 and 7.9 percent of nitrogen and phosphate fertilizers in the world (Table 8.2).

In Erazil fertilizer consumption has increased especially rapidly, over 18 percent for nitrogen and 24 percent growth rates for phosphorus. Mexican consumption has also increased rapidly but much less than that of Brazil, i.e. 10 percent growth rates for both nitrogen and phosphate fertilizers. Brazil and Mexico are responsible for 58 percent of Latin American nitrogen consumption and 78 percent of Latin American phosphate consumption (Figure 8.1 and 8.2 and Table 8.4).

The production increase of both major nutrients in Brazil has also been extremely rapid. Mexico, Argentina, Colombia, and Cuba demonstrated rapid production increases in at least one of the major nutrients during the last decade (Table 8.5).
